Key Corrections and Improvements

1. Risk Review Rate

The Power BI risk review calculation was checked to ensure it displays the correct percentage. The overall rate is:

2,352 risk-reviewed transactions ÷ 12,000 total transactions = 19.60%

The measure should use:

Risk Review Rate =

DIVIDE (

[Risk Review Transactions],

[Total Transactions],

0

)

and then be formatted as a percentage.

2. Transaction Date

Transaction_DateTime was converted to a proper datetime format in Python so that monthly trend analysis and time-based calculations work correctly.

3. Potential Outliers

The IQR method identified 1,474 potential transaction amount outliers. These were treated as potential high-value transactions requiring investigation rather than automatically being removed, since high transaction amounts can represent genuine banking activity.

4. Missing Values

The 96 missing Device_Type values and 96 missing Location values were identified and documented. They should not be silently replaced with invented values.

5. Findings Validation

Important Week 2 findings were checked using additional Week 3 analysis. For example:

- International transactions: 36.88% risk review rate
- Domestic transactions: 18.88%

- Mobile App success rate: 89.75%
- ATM success rate: 91.70%
- Everyday segment: 5,644 transactions
- SME average transaction value: approximately NGN 49,116
